(PRODUCT LEADERSHIP)

/universal intelligence

A framework-less protocol that gives models, tools, and agents one consistent contract across cloud, desktop, and browser environments.

STATUS	SCOPE	YEAR

300+

cataloged models

(01)

/the problem.

AI applications often bind product logic to one provider, runtime, or framework. Moving between a cloud model, a local model, and a browser model then requires different code and operational assumptions.

The product question was how to make that choice portable without hiding the capabilities teams still need to control.

(02)

/what i led.

- Defined Model, Tool, and Agent as the core product primitives and documented their contracts, compatibility rules, and runtime requirements.
- Shaped a catalog spanning 29 local models and 305 remote entries, with automatic selection for device, quantization, and inference engine.
- Planned parity across Python, JavaScript, cloud, desktop, and browser use cases, including MCP, A2A, OpenRouter, and Hugging Face integrations.
- Published version 1.2.0 to PyPI and npm with examples designed to reduce setup time.

(03)

/product decisions.

- Kept the protocol framework-less so teams could adopt the contract without replacing their stack.
- Made model selection declarative so developers could state requirements before choosing a provider or runtime.
- Treated Python and JavaScript parity as a product requirement.
- Included free-tier model options to reduce evaluation and prototyping costs.

(04)

/current limits.

The catalog is declarative and does not yet prove every model and runtime combination through automated tests. Streaming is also not fully wired across all paths. Those reliability gaps need to close before broader production use.
